Geometry/topology is everywhere

- Black Hole physics

- TQFT

,

- String Theory

- Loop Quantum Gravity

- ...

Let's start

- General relativity uses manifolds. For most physics students, this is the first encounter with differential geometry.
- Can we use manifolds to understand other theories (QFT for example)?

YES!

- Extended field theory vs Willsonian picture [Freed, Moore...]

Hierarchy of “knowledge”

- How much do we know about quantum gravity?
- How much do we know about QFT?
- How much do we know about quantum mechanics?

$$\frac{|\begin{array}{c} \circ \quad \circ \\ \hline \hline \end{array}\rangle + |\begin{array}{c} \times \quad \times \\ \hline \hline \end{array}\rangle}{\sqrt{2}}$$

- Should we understand quantum mechanics first?

In this talk we will not explore this fundamental question, but rather try to connect QM and manifolds in a more modest way.

Holography

- Our best understanding of quantum gravity: AdS/CFT
- Quantum dual to geometry
- We can calculate entanglement entropies from geometric data.

[RT,...]

- Holography played an important role in the past decade.
- ER=EPR?
- This all hints that there should be a connection between QM and manifolds.

Think about QM

- We have Hilbert space, states, inner product, entanglement, measurement, operators, unitarity...
- Actually, Hilbert space is (almost) all we need. Once we decide to use it, other things are natural.
- Entanglement: Natural consequence of $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2$ (and vector spaces are linear)
- Do we need linearity to capture entanglement?
- Categorical quantum mechanics

Quantum teleportation

A quick review

- Sketch of a protocol:

- Information is transferred, not matter. No super-luminous travelling, we need classical communication.

- In category theory, it is usually important to establish the commutativity of certain diagrams.
- Validity of quantum protocols can be expressed precisely in this way. [Abramski, Coecke]

Categories, finally

Def: A category consist of objects (a, b, c, \dots) and arrows (f, g, h, \dots) , together with rules:

- For every arrow f , there exist objects $\text{dom}(f)$, $\text{cod}(f)$
- For arrows $f : A \rightarrow B$ and $g : B \rightarrow C$ there is an arrow $g \circ f : A \rightarrow C$
- For every object a there is an arrow $\mathbf{1}_a : A \rightarrow A$
- Composition is associative
- For every arrow $f : A \rightarrow B$ we have $f \circ \mathbf{1}_a = \mathbf{1}_b \circ f$
- Important example: **Vect**_ℂ: objects are complex vector spaces, arrows are linear maps between vector spaces. We actually need **fdHilb**.

- We actually need dagger compact closed category with dagger biproducts. [Coecke, Abramski, Selinger]
- We will not give a precise definition of those categories, but only some intuition.
- Dagger: \dagger , in QM used for adjoints of operators
- A compact closed category is a symmetric monoidal category in which every object a has its dual a^* : Dual vector spaces; will play a role in measurement
- Biproducts: measurements “branching” and basis
(more about them later)
- But, where are promised **manifolds**?

Cobordisms

- We already mentioned in the context of TQFTs
- Best picture to have in mind: 
- Here we focus on a category of one dimensional cobordisms.
- For us 1-manifolds : one dimensional compact oriented topological manifolds, possibly with boundary.
- Objects of $1\mathbf{Cob}$: finite sequence of points with orientation (+ or -).
- For objects a and b of $1\mathbf{Cob}$, a 1-cobordism from a to b is a triple $(\mathcal{M}, f_0 : a \rightarrow \mathcal{M}, f_1 : b \rightarrow \mathcal{M})$, where \mathcal{M} is a 1-manifold and f_0, f_1 are embeddings.

\uparrow
orient. prev.

\hookrightarrow orient. rev
- Arrows of $1\mathbf{Cob}$ are equivalence classes of 1-cobordisms.

Coherence

- Not what you might expect when talking about quantum mechanics.
- We mean that there is a faithful functor from some freely generated category to our category that we use as a graphical language. [\[Petric, Zekic\]](#)
- For example, in a compact closed category, instead of using equalities that are valid, one can use pictures:

Category $1\text{Cob}_{\mathcal{G}}$

- We start from a group \mathcal{G} freely generated by Γ .
- A \mathcal{G} -component is a connected, oriented 1-manifold possibly with boundaries, together with an element of \mathcal{G} .
- A \mathcal{G} -cobordism from a to b is a finite collection of \mathcal{G} -components whose underlying manifold is \mathcal{M} , together with two embeddings $f_0 : a \rightarrow \mathcal{M}$ and $f_1 : b \rightarrow \mathcal{M}$ such that (\mathcal{M}, f_0, f_1) is a 1-cobordism from a to b .
- Objects: as before, arrows: equivalence classes of \mathcal{G} -cobordism .

Gauge Theory
???

Biproducts

- We have to deal with measurements: “branching”.
- To do so, we introduce biproducts.
- A zero-object is an object which is both initial and terminal.
- Products:

$$\begin{array}{ccccc} & & C & & \\ & \swarrow f & \downarrow h & \searrow g & \\ A & \xleftarrow{\pi_{A,B}^1} & A \times B & \xrightarrow{\pi_{A,B}^2} & B \end{array}$$

- Coproducts: injections
- Biproducts: products and coproducts, with certain “expected” equalities (assumed zero object).

Category $\mathbf{1Cob}_{\mathcal{G}}^{\oplus}$

- Objects are finite (possibly empty) sequences (a_0, a_1, \dots) of objects $\mathbf{1Cob}_{\mathcal{G}}$.
- Arrows from (a_0, \dots, a_{n-1}) to (b_0, \dots, b_{m-1}) are $m \times n$ matrices whose ij entry is a formal sum of arrows of $\mathbf{1Cob}$ from a_j to b_i .
- **Th:** The category $\mathbf{1Cob}_{\mathcal{G}}^{\oplus}$ has the structure of strict compact closed category with biproducts. The group of automorphisms of the object $+$ in this category is isomorphic to \mathcal{G} . Moreover, \dagger is definable in $\mathbf{1Cob}_{\mathcal{G}}^{\oplus}$, which makes it dagger strict compact closed category with dagger biproducts, while the automorphisms of $+$ are unitary.
- Summary: this is the desired category!

Free category

- We now come to a point to deal with coherence.
- We construct a category \mathcal{F} from the introduction (but we don't describe it here).
- Then, we can find a functor H that has just the right properties, and show:
- **Th:** The functor $H : \mathcal{F} \rightarrow \mathbf{1Cob}_{\mathcal{C}}^{\oplus}$ is faithful.
- Moral: we can use $\mathbf{1Cob}_{\mathcal{C}}^{\oplus}$ to check the validity of quantum protocols.

- For us, qubit (Q) is $+$. In general, this will not be enough to really simulate all the properties from Hilbert's state picture. [Baez]
- For example, one should insist on a unitary morphism $I \oplus I \rightarrow Q$.
- This does not prevent us from checking the validity of quantum protocols.
- For our purpose, we need four unitary operations (2×2 matrices in the Hilbert space picture).
- We therefore consider a free group \mathcal{G} with four generators

Teleportation protocol

\\particle creation as in Feynmann diagrams

$$\left(\begin{array}{c} \text{Diagram 1} \\ \beta_1 \end{array} \quad \begin{array}{c} \text{Diagram 2} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 3} \\ \beta_2 \end{array} \quad \begin{array}{c} \text{Diagram 4} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 5} \\ \beta_3 \end{array} \quad \begin{array}{c} \text{Diagram 6} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 7} \\ \beta_4 \end{array} \quad \begin{array}{c} \text{Diagram 8} \\ + \end{array} \right)^T$$

$$\left(\begin{array}{c} \text{Diagram 9} \\ \beta_1 \end{array} \quad \begin{array}{c} \text{Diagram 10} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 11} \\ \beta_2 \end{array} \quad \begin{array}{c} \text{Diagram 12} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 13} \\ \beta_3 \end{array} \quad \begin{array}{c} \text{Diagram 14} \\ + \end{array} \quad \begin{array}{c} \text{Diagram 15} \\ \beta_4 \end{array} \quad \begin{array}{c} \text{Diagram 16} \\ + \end{array} \right)^T$$

Teleportation protocol

- We then apply unitary corrections

$$\begin{pmatrix} \beta_1^{-1} \begin{array}{c} + \\ \bullet \\ | \\ \bullet \\ + \end{array} & 0 & 0 & 0 \\ 0 & \beta_2^{-1} \begin{array}{c} + \\ \bullet \\ | \\ \bullet \\ + \end{array} & 0 & 0 \\ 0 & 0 & \beta_3^{-1} \begin{array}{c} + \\ \bullet \\ | \\ \bullet \\ + \end{array} & 0 \\ 0 & 0 & 0 & \beta_4^{-1} \begin{array}{c} + \\ \bullet \\ | \\ \bullet \\ + \end{array} \end{pmatrix}$$

$$\left(\begin{array}{cccc} \text{Diagram 1} & \text{Diagram 2} & \text{Diagram 3} & \text{Diagram 4} \end{array} \right)^T$$

The diagrams are identical and represent a specific element in a matrix. Each diagram consists of a vertical line with four dots. The top dot is labeled '+'. The second dot from the top is labeled '+'. The third dot from the top is labeled '+'. The bottom dot is labeled '+'. A curved line connects the second and third dots, with a '-' sign above it. Below the curved line, the label β_1 is present. To the right of the vertical line, between the second and third dots, is a '+' sign. Below that, between the third and fourth dots, is a '+' sign. To the right of the vertical line, between the third and fourth dots, is a label β_1^{-1} .

- We can stretch elements of this matrix, thus obtaining the identity element in every matrix entry, thus proving the validity of the protocol.

Another story

- There are many other graphical languages for categorical quantum mechanics.
- ZX calculus
- “Kindergarten quantum mechanics”:

Entanglement swapping

- There are similar proposals: tensor networks, augmented space

- One does not include matrices of pictures in this approach, but rather consider case by case scenario, that is perfectly fine in many cases.
- In a way, our approach is more fundamental, but in principle our theorem is much stronger than the claim we use to check the validity of QM protocols.

Entanglement swapping

- Goal: interchange entanglement between two pairs of qubits:

- End result: same as top of this picture.

Conclusion

- We can use category $\mathbf{1Cob}_{\mathcal{E}}^{\oplus}$ to check the validity of a certain class of quantum protocols.
- This introduces another way in which manifolds can be relevant for quantum mechanics, and therefore a possible direction to think in quantum gravity.
- This is still not fully satisfactory picture of an interplay between QM and manifolds, it seems as we can improve it in the future.
- Increase dimensionality of manifolds?

Thank you for your attention!
